

standard hydrogen electrode

For solutions in protic solvents, the universal reference electrode for which, under standard conditions, the standard electrode potential (H^+ / H_2) is zero at all temperatures. The absolute electrode potential of the hydrogen electrode under standard conditions can be expressed in terms of thermodynamic quantities by applying a suitable Born–Haber cycle, thus:

$$E^\circ(\text{H}^+ / \text{H}_2)(\text{abs}) = \Delta_{\text{at}}G^\circ + \Delta_{\text{ion}}G^\circ + \frac{\alpha_{\text{H}^+}^{\text{o,S}}}{F}$$

where $\Delta_{\text{at}}G^\circ$ and $\Delta_{\text{ion}}G^\circ$ are the atomization and ionization Gibbs energies of H_2 , $\alpha_{\text{H}^+}^{\text{o,S}}$ is the real potential of H_2 in solvent S and F is the Faraday constant. The recommended absolute electrode potential of the hydrogen electrode is:

$$E^\circ(\text{H}^+ / \text{H}_2)^{\text{H}_2\text{O}}(\text{abs}) = (4.44 \pm 0.02) \text{ V} \quad \text{at} \quad 298.15 \text{ K}$$
